A **voltage regulator** is an electronic circuit which maintains the **output voltage (almost) constant** despite changes within some specified limits in the load current, input voltage, temperature, etc.

\[ V_O = v_I - v_{\text{regulator}} \]
\[ V_O = v_I - V_{\text{regulator}} \]
Regulator types

• **Parametric regulators** (with ZD, without active devices)

• **Linear voltage regulators** (contain active devices) – the transistors that adjust the output voltage to the default value operate in the linear regime (permanent conduction).

• **Switching voltage regulators** (contain active devices) – the main transistors that adjust the output voltage to the default value operate in switching regime, generally at a frequency $\geq 20$KHz.
Parametric voltage regulator

\[ i_Z = i_R - I_O \]
\[ i_R = \frac{v_I - V_Z}{R} \]
\[ i_Z = \frac{v_I - V_Z}{R} - I_O \]

\[ R = \frac{v_I - V_Z}{I_{Z\text{nom}} + I_O} \]

Please revisit the Zener Diode paragraph!
Op-amp voltage regulators

A reference voltage is always necessary in a voltage regulator

A better regulation can be provided if $R$ is replaced by a current source.
Op-amp voltage regulator

\[ V_O \neq V_{REF} \]

\[ v^+ = v^- \]
Op-amp voltage regulator – cont.

\[ V_O = \left( 1 + \frac{R_2}{R_1} \right) V_{\text{REF}} \]

\[ V_O = ? \]
Consider that $V_{REF}$ is given

\[ V_O < V_{REF} \]

\[ V_O = \frac{R_2}{R_1 + R_2} V_{REF} \]
Op-amp voltage regulator – cont.

Adjustable $V_O$, $V_O > V_{REF}$

- How does the circuit look like for adjustable $V_O$, $V_O < V_{REF}$?

- How does the circuit look like for adjustable $V_O$

  $V_{O\text{min}} < V_{REF}$ and $V_{O\text{max}} > V_{REF}$?
Increasing the output current

\[ I_{O\text{max}} = I_{O,A_{\text{max}}} \]

For common use op amp:

\[ I_{O,A_{\text{max}}} \approx 20\text{mA} \]

? Higher current in the load

Solutions:

• power op amp; e.g. TDA2030, up to 3.5A

• current amplifier between op amp and load (transistor)
BJT in permanent conduction \((a_F)\)

**nnp**

\[ v_{BE} > 0.6 \text{V}, \quad T-(a_F) \]
\[ v_{BE} < 0.6 \text{V}, \quad T-(off) \]

\[ i_E = i_C + i_B \]

Always valid

In the active region \((a_F)\)

\[ i_C = \beta i_B \]
\[ \beta = 100 \quad \text{as a rough guide} \]

\[ i_E = i_C + \frac{1}{\beta} i_C = i_C \left(1 + \frac{1}{\beta}\right) \approx i_C \]

\[ i_E = (\beta + 1) i_B \approx \beta i_B \]

**pnp**

\[ v_{BE} < -0.6 \text{V}, \quad T-(a_F) \]
\[ v_{BE} > -0.6 \text{V}, \quad T-(off) \]

\[ i_E \approx i_C \approx \beta i_B \]
\[ I_{O_{\text{max}}} = \beta I_{O,OA_{\text{max}}} \]

\( T \) – series pass transistor

\[ V_O = V_{\text{REF}} \]
The solution to use a BJT to increase the output current is applicable for all previous discussed voltage regulator configurations, without affecting the expression and value of the output voltage.
Overcurrent and shortcircuit protection

$R_L \rightarrow 0 \quad I_O \rightarrow \infty \quad \text{The current must be limited!}$

- oversee $I_O$
- when $I_O$ exceeds a default value, protection circuit triggers

$$R_P I_O < 0.6V; \quad T_P - (off); \quad I_P = 0$$

$$R_P I_O > 0.6V; \quad T_P - (a_F); \quad I_P > 0$$

$$I_{O_{\text{max}}} = \frac{V_{R_P}}{R_P} + I_P$$

$$I_{O_{\text{max}}} = \frac{0.7V}{R_P} + I_P \approx \frac{0.7V}{R_P}$$

When $I_O = I_{O_{\text{max}}}$

$R_L \downarrow, I_O \uparrow, I_O R_P \uparrow, I_P \uparrow, I_B \downarrow, I_O \downarrow \quad V_O \downarrow$
The output characteristic

- **voltage regulation region**
  \[ \nu_O = V_O, \quad I_O = \frac{V_O}{R_L} \]

- **knee point**
  \[ \nu_O = V_O, \quad I_O = I_{O_{\text{max}}} = \frac{0.7V}{R_P} \]

- **current limiting region**
  \[ \nu_O < V_O, \quad \nu_O = I_O R_L, \quad I_O = I_{O_{\text{max}}} + I_p \approx \frac{0.7V}{R_P} \]

- **short-circuit point**
  \[ \nu_O = 0 \]

\[ I_O = I_{O_{\text{sc}}} = \frac{0.7V}{R_P} + I_{O,A0\text{max}} - \frac{1}{\beta} \frac{0.7V}{R_P} \approx \frac{0.7V}{R_P} + I_{O,A0\text{max}} \approx \frac{0.7V}{R_P} \]
Maximum values of voltage, current, and power for $T$

$v_i \in (V_{I_{\text{min}}}; V_{I_{\text{max}}})$

- **maximum collector current:** $I_{C_{\text{max}}}$

- **maximum collector-emitter voltage**

  \[ V_{CE} = V_i - V_{RP} - V_O \]

  $V_{CE_{\text{max}}}$ appears for short-circuit to the output

  \[ V_{CE_{\text{max}}} = V_{I_{\text{max}}} - V_{RP} = V_{I_{\text{max}}} - 0.7V \approx V_{I_{\text{max}}} \]

- **maximum power dissipated by the transistor**

  \[ P_{dT} \approx I_C V_{CE} \]

  appears for short-circuit to the output

\[ P_{dT_{\text{max}}} \approx I_{O_{\text{max}}} V_{I_{\text{max}}} \]
Selecting the series pass transistor

In the transistor data-sheets we can find absolute maximum ratings for

- collector current \( I_{C\text{max}} \)
- collector-emitter voltage \( V_{CE0} \)
- power \( P_{d\text{tot}} \)

\( T \) should be selected so that:

\[
I_{C\text{max}} > 2I_{O\text{max}}
\]

\[
V_{CE0} > V_{CE \text{max}}
\]

\[
0.4P_{d\text{tot}} \geq P_{dT \text{max}}
\]

Pay attention for dissipated power. The value in the data-sheet refers to the maximum power when \( T \) is mounted on an infinite area heatsink. In practice the maximum power to be consider is \( P_{d\text{max}} \approx 0.4P_{d\text{tot}} \) (acceptable size heatsink).
Complementary Silicon Power Transistors

Complementary silicon power transistors are designed for general-purpose switching and amplifier applications.

Features
- DC Current Gain – $h_{FE} = 20\text{–}70$ @ $I_C = 4$ Adc
- Collector–Emitter Saturation Voltage – $V_{CE(sat)} = 1.1$ Vdc (Max) @ $I_C = 4$ Adc
- Excellent Safe Operating Area
- Pb–Free Packages are Available*

Maximum ratings are those values beyond which device damage can occur. Maximum ratings applied to the device are individual stress limit values (not normal operating conditions) and are not valid simultaneously. If these limits are exceeded, device functional operation is not implied, damage may occur and reliability may be affected.
Consider the O.A. – ideal.
a) Find the expression and range of values in which $V_O$ can be adjusted if $R_L$ is large enough to maintain $T_p$ – off. 
b) What components in the circuit compose the protection circuit? 
c) What is the maximum value of the output current? Assume that the base currents of $T$ and $T_p$ can be neglected. Assuming the cursor of $P$ in the middle, compute the maximum power dissipation on $T$ for $R_{L1}=0.2 \text{ k}\Omega; R_{L2}=20 \text{ }\Omega; R_{L3}=0 \text{ }\Omega$. 

Exercise
Voltage reference

\[ V_{REF} = (1 + \frac{R_2}{R_1}) V_Z = \left(1 + \frac{2.67}{5.9}\right) \cdot 6.2 = 9 \text{V} \]

\[ I_Z = \frac{V_{REF} - V_Z}{R_3} = \frac{9 - 6.3}{374} = 7.5 \text{mA} \]
